ABSTRACT

Disclosed herein, among other things, is a method performed
by a user equipment (UE) for providing to a network channel
station information (CSI). The method comprises: receiving
from the network two measurement power offsets, a first
measurement power offset and a second measurement power
offset; selecting one of said two measurement power offsets;
computing CSI using the selected measurement power offset;
and transmitting to the network the determined CSI.

SYSTEMS AND METHODS FOR DETERMINING MEASUREMENT POWER OFFSETS

CROSS REFERENCE TO RELATED APPLICATION(S)

This application is a 35 U.S.C. §371 National Phase Entry Application from PCT/SE2013/050950, filed Aug. 5, 2013, which claims priority to U.S. provisional patent application No. 61/683,584, filed on Aug. 15, 2012. The above identified applications are incorporated by reference in their entirety.

TECHNICAL FIELD

Aspects of this disclosure relate to systems and methods for determining measurement power offsets in network that uses multiple pilots, such as, for example, a multi-antenna communication system.

BACKGROUND

Multiple input multiple output (MIMO) is an advanced antenna technique to improve the spectral efficiency and thereby boosting the overall system capacity. The MIMO technique uses a commonly known notation (M×N) to represent MIMO configuration in terms number of transmit (M) and receive antennas (N). The common MIMO configurations used or currently discussed for various technologies are: (2×1), (1×2), (2×2), (4×2), (8×2) and (8×4). The configurations represented by (2×1) and (1×2) are special cases of MIMO and they correspond to transmit diversity and receiver diversity respectively. The configuration (2×2) is used in WCDMA release 7 and configurations ((4×4), (4×2) (4×1)) are being defined in Third Generation Partnership Project (3GPP) release 11.

Currently a 4Tx transmissions scheme for High-Speed Downlink Packet Access (HSDPA) is discussed within 3GPP standardization. Previous versions of the specification supported up to 2 TX antenna transmissions. In order to support 4Tx MIMO transmissions, it is necessary to obtain 4 channel estimates in order to characterize each of the spatial layers, which will require new pilot signals to be defined. Pilots are needed for two main functionalities; channel state information (CSI) estimation through channel sounding where rank, a channel quality indicator (CQI) (also referred to as channel quality information) and a precoding control index (PCI) are estimated and channel estimation for demodulation purposes.

For 4 branch MIMO, at least two different approaches are possible (1) Common pilots for both CSI and channel estimation for data demodulation and (2) Common pilots for CSI estimation and additional pilots for channel estimation for data demodulation.

In the above context, “common pilots” refer to pilots that are made available to all users and which are transmitted without user specific beamforming.

Common pilots may be transmitted at instances in which legacy users (Release 7 MIMO and Release 99), who are not able to demodulate 4TX transmissions are scheduled. These legacy users cannot make use of the energy in the common pilots. However, the energy in the additional common pilots will reduce the amount of energy available for High-Speed Physical Downlink Shared Channel (HS-PDSCH) scheduling to the legacy users. Moreover, the additional pilots cause interference to these users. Therefore, to minimize performance impacts to non 4TX users, it is essential that the power of the common pilots can be reduced to a low value.

In a High-Speed Downlink Packet Access (HSDPA) system, the user equipment (UE) (e.g., communication device) has to periodically report a channel quality indicator (CQI). The period is configured by the higher layers. For the purpose of channel quality reporting the UE has to know the powers of the pilots and the measurement offset (a.k.a., measurement power offset).

In Release 7 MIMO (2×2), for the purpose of CQI reporting, the UE shall assume a total transmit power of HS-PDSCH ($P_{HSPDSCH}$) is given by:

$$P_{HSPDSCH} = P_{CPICH} + \Gamma \text{ in dB,}$$

where the total transmit power is assumed to be evenly distributed among the HS-PDSCH codes corresponding to the reported CQI value, and the measurement power offset Γ (i.e., an offset value) is signaled by higher layers. P_{CPICH} denotes the combined transmit power of a set of CPICH(s) (e.g., a primary CPICH and three secondary CPICHs) used for MIMO operation of the High-Speed Downlink Shared Channel (HS-DSCH).

The base station (e.g., Node B) sends the measurement power offset information through higher order signaling for example Radio Resource Control (RRC) messages. The actual measurement power offset can vary from TTI to TTI since HS-PDSCH power depends upon power transmitted by Node B when user is scheduled. A user can be scheduled every TTI. To reduce overhead, the measurement power offset is signaled preferably only at the start of an HSDPA session. Therefore, the Node B re-computes the actual CQI based on the current or recent measurement power offset and the signaled measurement power offset. The Node B knows the signaled measurement power offset. In a four branch MIMO, it was decided to use two types of pilot solutions. The Node B informs the UE which one of the two to use. In each case, the measurement power offset computation is different. Hence a new method to determine the measurement power offset and convey this information is desired.

SUMMARY

Described herein are, among other embodiments, various embodiments for computing measurement power offset and conveying this information to UE. The various embodiment may be utilized in a mixed pilot scenario—e.g., the case of common pilots and scheduled or demodulation common pilots.

In one aspect, a method performed by a network node is provided. In some embodiments, the method includes: determining whether a first scheme (scheme-1) or a second scheme (scheme-2) should be used to calculate a measurement power offset (MPO). In some embodiments, this step consists of (or comprises) determining whether a determined signal quality value (SQV) is above a threshold (T). In other embodiments, the step consists of or comprises determining whether a UE recommended scheme-1 or scheme-2. In response to determining that scheme-1 should be selected (e.g., in response to determining that the SQV is above T), the network node uses scheme-1 to calculate the MPO. Otherwise, in response to determining that scheme-2 should be selected (e.g., in response to determining that the SQV is not above T), the node uses scheme-2 to calculate the MPO. The node then sends to the UE (directly or indirectly) a message containing the calculated MPO.

In another aspect, a network node is provided. In some embodiments, the network node comprises a data storage system and a data processing system. The data storage system comprises instructions executable by the data processing sys-

3

tem whereby the network node is operative to: determine a first measurement power offset, Γ_1 , based on a first scheme, scheme-1; determine a second measurement power offset, Γ_2 , based on a second scheme, scheme-2; and inform the UE of Γ_1 and Γ_2 .

In another aspect, a method performed by a first network node for sending to a UE two measurement power offsets: a first measurement power offset, Γ_1 , and a second measurement power offset, Γ_2 , is provided. In some embodiments, the method includes: receiving Γ_1 and Γ_2 from a calculating node that calculated Γ_1 and Γ_2 , wherein the Γ_1 and Γ_2 are calculated based on a first scheme, scheme-1, and a second scheme, scheme-2, respectively; including Γ_1 and Γ_2 in a Radio Resource Control, RRC, message; and transmitting to the UE the RRC message.

In another aspect, a first network node for sending to a UE two measurement power offsets: a first measurement power offset, Γ_1 , and a second measurement power offset, Γ_2 , is provided. In some embodiments, the first network node is adapted to: receive Γ_1 and Γ_2 from a calculating node that calculated Γ_1 and Γ_2 ; include Γ_1 and Γ_2 in a Radio Resource Control, RRC, message; and transmit the RRC message towards the UE.

In another aspect, a method performed by a UE is provided. In some embodiments the method includes: the UE receives a first measurement power offset (MPO1) and a second measurement power offset (MPO2) from a network node. The UE then selects one of MPO1 and MPO2. In some embodiments, the selection is based on whether a determined SQV is above a threshold value (T), and in other embodiments the determination is based on a received HS-SCCH order. In response to selecting MPO1, the UE uses MPO1 for CSI estimation, but not MPO2 (e.g., uses MPO1 to determine one or more of CQI, PCI, and RI). Otherwise, in response to selecting MPO2, the UE uses MPO2 for CSI estimation, but not MPO1 (e.g., uses MPO2 to determine one or more of CQI, PCI, and RI). Next, the UE sends to the network the CSI (e.g., a CSI report identifying CQI, PCI). The UE may also send to the network a message comprising information (e.g., a sing bit of information) indicating which measurement power offset was selected (i.e., MPO1 or MPO2).

In another aspect, a UE is provided. In some embodiments, the UE comprises a data storage system and a data processing system, the data storage system storing instructions executable by the data processing system whereby the UE is operative to: receive from a network node two measurement power offsets, a first measurement power offset and a second measurement power offset; select one of said two measurement power offsets; use the selected measurement power offset for channel station information, CSI, estimation; and transmit the CSI.

An advantage of this disclosure is that the impact of 4 TX MIMO on legacy terminals arising from the need for additional pilots can be kept on a reasonable level. At the same time as high power pilots can be provided to the terminal as an aid for data detection.

The above and other aspects and embodiments are described below with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated herein and form part of the specification, illustrate various embodiments.

FIG. 15 is a flow chart illustrating a process, according to some embodiments, that is performed by a network node (e.g., an RNC).

DETAILED DESCRIPTION

Referring to FIG. 13, FIG. 13 shows an example network 100 in which the methods described herein may be employed. Network 100 is a wireless communication system that enables a wireless communication device 100 (also referred to as user equipment (UE)) to communicate with, among other devices, a host 112 connected to a packet data network 110 (e.g., the Internet). In the example shown, network 100 includes a radio access network (RAN) that includes a relay node 105, a base station 102 (also referred to as Node B), a radio network controller (RNC) 106, and a core network 107.

I. Overview of Pilot Design Schemes for MIMO Systems

As mentioned above, at least two pilot design schemes are contemplated: 1) common pilots for CSI estimation and data demodulation and 2) common pilots for CSI estimation and additional pilots without precoding for data demodulation (scheduled pilots demodulation common pilots).

1. Common Pilots for CSI Estimation and Data Demodulation

FIG. 1 is diagram of a common pilot design system. At the Node B 102 transmitter 191, known pilot symbols are transmitted for channel sounding. The UE 101 receiver 192 receives the pilot symbols and the UE determines channel quality (typically SINR) from channel sounding, and computes a preferred precoding matrix and CQI for the next downlink transmission. This information is conveyed to the Node B through a feedback channel 177. The Node B processes this information and determines the precoding matrix and modulation and some other parameters (e.g., transport block size, etc.) and conveys this information to the UE through a downlink control channel. Data is transmitted with the modulation and coding rate indicated in the downlink control channel. The data is pre-multiplied by precoding vector/matrix before passing to the antenna ports. For data demodulation, the UE receiver 192 estimates the channel for data demodulation from the common pilot symbols.

Common pilot only solutions will have a negative impact on legacy users unless the power on the additional pilots is minimal. FIG. 2 shows the performance of a pilot reduction scheme on the sector throughput with different number of users per sector. For this simulation, it is assumed that all the users are Release-7 MIMO capable with 2 receive antennas. The additional interference due to third and fourth pilots is considered with different power levels. The pilot powers for the first and the second antennas are set to -10 dB and -13 dB respectively. As indicated, as the power of the additional pilots is decreased, the impact on the system throughput performance is less. For example, if the pilot power is around -19 dB, then the impact on the legacy users is almost negligible.

However, if the power is minimal, then the demodulation performance of 4TX users will be adversely impacted. FIGS. 3 and 4 show the Link level throughput for a UE with 3 different C/I for 4×4 MIMO and 4×2 MIMO. As discussed above, when operating with common pilots it will be necessary to minimize the power transmitted on the 3rd and 4th pilots in order to minimize impact to legacy users.

The performance with reduced pilot powers for 3rd and 4th antennas while keeping the pilot powers for 1st and 2nd antennas as -10 and -13 dB, respectively, was plotted. As indicated, as the pilot powers are reduced, the performance degrades due to bad channel estimation for CQI and data demodulation. The degradation is severe at high C/I compared to low C/I region. This is because at high C/I, there is a high probability of rank 3 and rank 4 transmissions and/or high data rates, which require a larger amount of pilot power energy. On the other hand, low data rates and/or rank selections, which occurs at low C/I can be demodulated with a lower amount of pilot energy (i.e. a higher traffic to pilot ratio).

Introduction of additional pilots when any 4 branch MIMO user is scheduled may cost some additional overhead and may not give benefit for all the scenarios. In reality, a high amount of pilot power is required when the UE is attempting to demodulate high data rates with high rank.

2. Common Pilots for CSI Estimation and Additional Pilots for Data Demodulation.

The system diagram in this scheme is shown in FIG. 5. Similar to the common pilot scheme, known pilot symbols are used for channel sounding, the UE conveys the preferred precoding matrix, CQI through the feedback channel (e.g. HS-DPCCH). For downlink data transmission, The Node B uses this information and chooses the precoding matrix, CQI and the transport block size. For data transmission, data is multiplied by the precoding matrix selected by the Node B then transmitted. In addition to the data, additional pilots similar to common pilots without precoding are transmitted with high power from all or few subset of antennas (for example 3rd and 4th antennas). These additional pilots are called scheduled pilots. Using these additional pilots, the UE estimates the channel for data demodulation purposes.

FIG. 6 shows link performance for a solution based on common pilots for CSI estimation and scheduled pilots for data demodulation. Note that with ideal channel estimation, the performance of scheduled common pilot solution is always inferior to the common pilot solution with power of -13 dB on third and fourth antennas. This is due to the additional power allocated to these scheduled pilots. Additionally, the performance of schedule pilots with realistic estimation is close to that of common pilot solution with pilot power of -13 dB. Hence this solution is attractive in terms of link performance for four branch MIMO system.

The performance gains with scheduled pilots are almost negligible at low to medium geometries. Hence, scheduled pilots may not be needed for all geometries.

From FIG. 6 it can be observed that for low to medium geometries/data rates, common pilot solution is sufficient to give a reasonable performance. Additional pilots are more necessary at high SNR or for high data rate applications. To show the impact of reduced pilot power for high data rate application we plotted the 4×4 MIMO link performance with pilot powers $[-10 -13 -19 -19]$ dB with two link adaptation (LA) algorithms. In the first link adaptation algorithm all modulations are considered i.e. QPSK, 16 QAM and 64 QAM, while in the second link adaptation algorithm; we consider only QPSK and 16 QAM. FIG. 7 shows the performance with these two link adaptation algorithms. The results with perfection estimation are also shown. It can be observed that at low and medium geometries the performance of the two link adaptation algorithms is same, while at high geometries the performance of the link adaptation algorithm without 64 QAM performs better. The performance degradation with conventional LA is around 33% and while with the modified LA is around 16% compared to the perfect estimation.

One solution is to use both common pilots plus scheduled pilots. The Node B can decide based on some criteria and decide which scheme to use. The UE can identify which scheme is used by looking at the High-Speed Shared Control Channel (HS-SCCH) control channel or by some HS-SCCH orders.

II. Conveying Information about Demodulation Pilots

According to the simulation results presented and the discussion, common pilots are transmitted for CSI estimation and additional pilots are chosen for data demodulation based on user information available at the Node B. Examples of user information include: CSI reports (e.g. CQI, PCI, RI etc), user signal quality in general, data rate, service type (e.g. whether requires higher data rate or not), geometry (e.g. ratio of received power from own cell to that from neighboring cells), etc. The signal quality can be expressed in terms of for example CQI, SINR, SNR, BLER, BER, ACK/NACK for DL signal reception, CPICH measurements (CPICH RSCP, CPICH Ec/No) etc. For example, when the users are nearer to the cell center (high geometries hence higher order modulations) additional pilots can be transmitted for data demodulation. Otherwise common pilots are sufficient for data demodulation.

FIG. 8 shows a message sequence chart. In this case, common pilots **801** are transmitted from the Node B continuously for CSI estimation. The UE computes the channel state information: channel quality indicator (CQI), Precoding control index (PCI) and Rank information (RI) through these channels and report this information **802** in uplink feedback channel (HS-DPCCH). Once the Node B receives this information, the Node B scheduler decides whether common pilots are needed or scheduled pilots are needed for demodulation. This is done based on, for example, one or more of SNR, user location or modulation and code rate assigned etc. If the demodulation pilots are needed to be transmitted, the network (e.g. Node B) will convey this information through separate signaling using an HS-SCCH order **803** (e.g., special bit pattern for switching on demodulation pilots). If the UE is able to decode this message it will send an ACK **804** to this order through the feedback channel (HS-DPCCH). The data is transmitted there on HS-PDSCH **805**. The UE can use the scheduled common pilots for demodulation until again informed by the Node B to use common pilots.

III. Conventional Method Computing Measurement Power Offset

As stated above, the Node B re-computes the actual CSI using the UE reported CSI, actual or recent measurement power offset based on current transmitted power levels, and signaled measurement power offset (i.e. value signaled to UE for CSI measurement). In this section we describe how the Node B can compute the measurement power offset (Γ). For Release 7 MIMO, the Node B computes the measurement power offset by the following equation:

$$\Gamma = P_{HSPDSCH} - P_{CPICH} \text{ in dB,}$$

where $P_{HSPDSCH}$ is the total transmit power at the Node B and is assumed to be evenly distributed among the HS-PDSCH codes. P_{CPICH} denotes the combined transmit power of the set of CPICH(s) (primary C-PICH, S-CPICH on 2nd) used for MIMO operation of HS-DSCH.

For conveying this measurement power offset information to UE, Node B uses Radio Resource Control (RRC) signaling.

IV. Methods of Computing Measurement Power Offset, Signaling Over Iub and Signaling to UE

A. Embodiment 1

This embodiment may be implemented, at least primarily, on a radio node serving a UE. For example, it may be implemented in a relay node (see e.g., node 105 of FIG. 13) serving UE, but it can also be implemented in RNC 106, a donor node controlling a relay node (see e.g., node 102 of FIG. 13), or other network node.

As shown in FIG. 13, relay node (RN) 105 is connected to a network via a wireless interface 117 to a donor node 102 (also referred to as donor Node B (DNB)). The DNB 102 provides backhaul transport for the RN 105 and all the UEs 101 connected to the RN 105.

In this embodiment, the method comprises computing a measurement power offset (MPO) based on one or more criteria or condition. For example, the serving radio node (e.g. Node B 102 or RN 105) computes the measurement power offset: (1) using a first computing scheme, provided that only common pilots are used and (2) using a second computing scheme, provided that common and demodulation pilots are used.

The method, according to this one embodiment, requires the network node (e.g. Node B/RN) to adapt the scheme for computing measurement power offset based on at least one criterion (e.g. signal quality, etc.).

The decision to use demodulation pilots may be based on one or more criteria as discussed above (e.g. downlink signal quality, type of service, data rate, etc). The DL signal quality can be determined from the UE reported measurements or estimation in the network.

The decision to use demodulation pilots or adapt the scheme for computing the measurement power offset can also be based on UE recommendation. For example, the two schemes for computing measurement power offset can be predefined (e.g. represented by identifiers 0 and 1). The UE, based on suitable criteria (e.g. DL signal quality, data rate, type of service etc), can recommend to the network whether the network should use first the computing scheme (0) or use the second computing scheme (1). The UE may send this recommendation over HS-DPCCH or over any channel directly to the node receiving CSI reports (e.g. Node B). The network (e.g. Node B) can either use its own scheme selection criteria (as explained above), use the UE recommendation, or

some combination of its own criteria and the UE recommendation to decide which scheme to use for computing the measurement power offset.

The computed measurement power offset set can also be signaled by the node computing the measurement power offset to another node. The computing node or the other node may then signal the derived or computed measurement power offset to the UE. For example the computing node and the other nodes can be Node B 102 and RNC 106, respectively. In this case, the measurement power offset is signaled over the Iub interface 107 between the Node B and RNC. Furthermore, in this case, the measurement power offset received at the RNC is signaled to the UE using RRC. In another example, the computing node itself may signal the measurement power offset to the UE (e.g. the Node B may signal the measurement power offset to the UE using the media access control (MAC) layer). The method is further illustrated through the following example.

When the UE is not using additional demodulation pilots (i.e., when not signaled by Node B), the measurement power offset (Γ) computation may be computed by the following equation:

$$\Gamma = P_{HSPDSCH} - P_{CPICH} \text{ in dB,} \quad (1)$$

where $P_{HSPDSCH}$ is the total transmit power at the Node B side and is assumed to be evenly distributed among the HS-PDSCH codes. P_{CPICH} denotes the combined transmit power of the set of CPICH(s) (primary C-PICH, S-CPICH on 2nd, 3rd and 4th transmit antennas) used for MIMO operation of HS-DSCH.

When demodulation pilots are used for data demodulation (e.g., the Node B decides to use demodulation pilots), then the measurement power offset (Γ) may be computed by the following equation.

$$\Gamma = P_{HSPDSCH} - P_{CPICH} - P_{DPICH} \text{ in dB,} \quad (2)$$

where $P_{HSPDSCH}$ is the total transmit power at the Node B side and is assumed to be evenly distributed among the HS-PDSCH codes, P_{CPICH} denotes the combined transmit power of the set of CPICH(s) (primary C-PICH, S-CPICH on 2nd) used for MIMO operation of HS-DSCH, and P_{DPICH} denotes the combined transmit power of the set of D-CPICH(s) (demodulation pilots on 3rd and 4th antennas) used for MIMO operation of HS-DSCH. In the above equation, it is assumed that demodulations pilots are used on 3rd and 4th antennas.

Hence in this case, Node B has to signal two times the measurement offset to the RNC and to the UE via RNC. One is at the beginning and other once Node B gets an ACK for the HS-SCCH order. The UE has to use the most recently received measurement power offset from the network (e.g. from RNC) for estimating the CSI.

For re-computing the actual CSI, the Node B also uses the same method of measurement power offset which is used for signaling the measurement power offset to the UE for CSI estimation.

Accordingly, in some embodiment, the Node B or other network node, may perform the following process 900 (see FIG. 9). In step 902, the Node B determines a signal quality value (SQV) (optional step). In step 904, the Node B determines whether it should use a first scheme or a second scheme to calculate the measurement power offset (MPO). In some embodiments, step 904 consists of or comprises the Node B determining whether the SQV is above a threshold (T). In step 908, in response to determining that the first scheme (scheme-1) should be selected (e.g., in response to determining that the SQV is above T), the Node B uses scheme-1 to calculate the MPO. In step 910, in response to determining that the second

scheme (scheme-2) should be selected (e.g., in response to determining that the SQV is not above T), the Node B uses scheme-2 to calculate the MPO. In step 912, the Node B sends to the UE (directly or indirectly) a message containing the calculated MPO.

B. Embodiment 2

This embodiment involves: 1) a radio node (e.g. a Node B, a relay node) serving a UE; 2) the UE, which receives measurement power offsets; and 3) another node (e.g. RNC, donor node controlling relay node), which communicates with the radio serving node and UE. In this embodiment, the network signals two measurement power offsets to the UE for CSI estimation. The UE selects, based on one or more criteria, one of the measurement power offsets and then uses the selected measurement power offset (e.g., for CSI estimation). The one or more criteria can be pre-defined or signaled to the UE, or combination thereof. For example, the criteria can be based on signal quality (e.g. BLER, SINR, SNR, etc), service type (e.g. low data rate, high data rate, etc). For example, a criteria can be: if signal quality is above a threshold, then first power offset is used by the UE for CSI estimation, otherwise second power offset is used by the UE for CSI estimation. The threshold in terms of signal quality can also be pre-defined or signaled to the UE.

Accordingly, the UE may perform the process 1000 (see FIG. 10) and a network node 102, 105, 106 may perform process 1400 (see FIG. 13).

Referring now to process 1000 (FIG. 10), in step 1001, the UE receives a first measurement power offset (MPO1) and a second measurement power offset (MPO2). In step 1002 (optional), the UE determines one or more of: a signal quality value (SQV) (i.e., a value representative of signal quality), a service type, and a data rate. In step 1003 (optional), the UE receives an HS-SCCH order. In step 1004, the UE determines whether it should select MPO1 or MPO2. In some embodiments, in step 1004, the UE determines whether it should select MPO1 or MPO2 based on the determined SQV, service type, and/or data rate. For example, in some embodiments step 1004 consists of or comprises the UE determining whether the SQV is above a threshold value (T). In some embodiments, step 1004 consists or comprises the UE selecting determines whether it should select MPO1 or MPO2 based on the received HS-SCCH order. In step 1008, in response to determining that MPO1 should be selected (e.g., in response to determining that the SQV is above T), the UE selects MPO1 and uses MPO1 for CSI estimation, but not MPO2 (e.g., uses MPO1 to determine one or more of CQI, PCI, RI). In step 1010, in response to determining that MPO2 should be selected (e.g., in response to determining that the SQV is not above T), the UE selects MPO2 and uses MPO2 for CSI estimation, but not MPO1 (e.g., uses MPO2 to determine one or more of CQI, PCI, RI). In step 1012, the UE sends to the network a CSI report (e.g., a message identifying CQI, PCI). In step 1014 (optional), the UE may also send to the network a message indicating which power offset was selected.

As illustrated in FIG. 10, according to some aspects of this embodiment, the UE may also report to the network the selected measurement power offset (i.e. first or second) used for estimating the reported CSI. For example, the expression of the two offsets can be pre-defined and can be represented by identifiers 0 and 1 respectively (i.e., 1 bit). As an example, the UE may indicate that it has used first power offset for the reported CSI if the said first power offset is used. This indication requires at least one bit of signaling in addition to CSI

reports. This will enable the network (e.g. Node B) to use the same power offset to re-compute the actual CSI. The network node (e.g. RNC) may also configure the UE whether to indicate which power offset it (UE) uses for CSI estimation.

In some aspects of this embodiment, signaling of the two measurement power offsets between network nodes may be required, e.g. between Node B and RNC, between relay and donor node (aka controlling node). For example Node B signals the two offsets to the RNC over Iub interface. The RNC then signals the received values to the UE via RRC. The RNC may also signal them to another RNC which may signal it to the UE. This is described below.

Referring now to process 1400 (FIG. 14), in step 1401, a network node (e.g., the Node B) computes a first measurement power offset (MPO1—a.k.a., “T” or “T1”).

In step 1402, the network node computes a second measurement power offset (MPO2 a.k.a., “T1” or “T2”).

In step 1403, the network node informs the UE of MPO1 and MPO2, either directly or indirectly (e.g., indirectly via RNC). In both cases the measurement power offsets may be signaled using MAC and RRC messages, respectively. In some embodiments, the network node informs the UE of MPO1 at a different time than the time at which the network node informs the UE of MPO2. The two measurement power offsets computations are according to the following equations:

$$MPO1 = \Gamma1 = P_{HSPDSCH} - P_{CPICH} \text{ in dB, and}$$

$$MPO2 = \Gamma2 = P_{HSPDSCH} - P_{CPICH} - P_{DPICH} \text{ in dB}$$

where $P_{HSPDSCH}$ is the total transmit power at the Node B side and is assumed to be evenly distributed among the HS-PDSCH codes, P_{CPICH} denotes the combined transmit power of the set of CPICH(s) (primary C-PICH, S-CPICH on 2nd, 3rd and 4th transmit antennas) used for MIMO operation of HS-DSCH for computing $\Gamma1$ and for computing $\Gamma2$, it consists of only P-CPICH and S-CPICH on 2nd antenna.

As one example, the network node (e.g., Node B) sends the two measurement power offsets (MPO1 and MPO2) indirectly to the UE via RNC.

Referring now to FIG. 14B, which illustrates a process 1450, in some embodiments, the network node determines, based on one or more criteria (e.g., downlink signal quality, service type, data rate), which of the two MPOs (MPO1 or MPO2) the UE should use in computing CSI and transmits to the UE an HS-SCCH order that, as discussed above, informs the UE about which measurement power offset the network node has determined the UE should use in computing the CSI (step 1404). As also discussed above (see FIG. 10), which MPO the UE will select to use (i.e., MPO1 or MPO2) may depend on some condition or criteria (e.g. based on signal quality).

The UE computes the CSI based on the selected measurement power offset and reports the computed CSI to the network node. The UE may also indicate to the network as to which power offset was used for estimating the reported CSI. Accordingly, in step 1405, the network node receives the CSI determined by the UE and information (e.g., a single bit) identifying the MPO that the UE used in determining the CSI. In step 1406, the network node re-computes the CSI using the MPO used by the UE to perform the CSI estimation.

Referring now to FIG. 15, FIG. 15 illustrates a process, according to one embodiment, for informing the UE of the two MPOs (MPO1 and MPO2). The process may begin in step 1502, where RNC 106 receives, via an Iub interface 107, from Node B 102 (i.e., the “calculating node”) the measurement power offsets (i.e., MPO1 and MPO2) calculated by

11

Node B **102** as described above with reference to process **1400**. In step **1504**, RNC **106** includes the received measurement power offsets in a message (e.g., an RRC message as described in FIG. **15**). In step **1506**, RNC **106** transmits the message that includes the two measurement power offsets (i.e., the message is transmitted so that the UE **101** will receive the two MPOs). For example, in one embodiment, the message is transmitted to the UE via a base station. In another embodiment, the message is sent to another RNC (not shown) that then transmits the two MPOs to UE **101**.

Referring now to FIG. **11**, FIG. **11** illustrates a block diagram of a network node **1100** (e.g., a base station **102**, a relay **105**, a RNC **106**) according to some embodiments. As shown in FIG. **11**, the network node **1100** includes: a data processing system **1102**, which may include one or more data processing devices each having one or more microprocessors and/or one or more circuits, such as an application specific integrated circuit (ASIC), Field-programmable gate arrays (FPGAs), etc and a data storage system **1106**, which may include one or more computer-readable mediums, such as non-volatile storage devices and/or volatile storage devices (e.g., random access memory (RAM)). Network node **1100** may also include a transceiver **1105** for wirelessly transmitting and receiving data and a network interface **1111** for connecting network node **1100** to a network **110** (e.g., an Internet Protocol (IP) network).

In embodiments where data processing system **1102** includes a microprocessor, a computer program product is provided, which computer program product includes: computer readable program code **1143** (i.e., instructions), which implements a computer program, stored on a computer readable medium **1142**, such as, but not limited, to magnetic media (e.g., a hard disk), optical media (e.g., a DVD), memory devices (e.g., random access memory), etc. In some embodiments, computer readable program code **1143** is configured such that, when executed by data processing system **1102**, code **1143** causes the network node **1100** to perform the steps described herein (e.g., one or more steps shown in the flowcharts and/or described in connection with FIGS. **9**, **14A**, and **14B**). In other embodiments, network node **1100** may be configured to perform steps described herein without the need for code **1143**. For example, data processing system **1102** may consist merely of specialized hardware, such as one or more application-specific integrated circuits (ASICs). Hence, the features of the present invention described above may be implemented in hardware and/or software. For example, in some embodiments, the functional components of network node **1100** described above may be implemented by data processing system **1102** executing computer instructions **1143**, by data processing system **1102** operating independent of any computer instructions **1143**, or by any suitable combination of hardware and/or software.

Referring now to FIG. **12**, FIG. **12** illustrates a block diagram of a UE **101** according to some embodiments. As shown in FIG. **12**, the UE **101** may include: a data processing system **1202**, which may include one or more data processing devices each having one or more microprocessors and/or one or more circuits, such as an application specific integrated circuit (ASIC), Field-programmable gate arrays (FPGAs), etc; a data storage system **1206**, which may include one or more computer-readable mediums, such as non-volatile storage devices and/or volatile storage devices (e.g., random access memory (RAM)); and a transceiver **1205** for transmitting data to (and receiving data from) base stations (e.g., base station **102** or **105**).

In embodiments where data processing system **1202** includes a microprocessor, a computer program product is

12

provided, which computer program product includes: computer readable program code **1243** (i.e., instructions), which implements a computer program, stored on a computer readable medium **1242**, such as, but not limited, to magnetic media (e.g., a hard disk), optical media (e.g., a DVD), memory devices (e.g., random access memory), etc. In some embodiments, computer readable program code **1243** is configured such that, when executed by data processing system **1202**, code **1243** causes the UE **101** to perform the steps described herein (e.g., one or more steps shown in the flowcharts and/or described in connection with FIG. **10**). In other embodiments, UE **101** may be configured to perform steps described herein without the need for code **1243**. For example, data processing system **1202** may consist merely of specialized hardware, such as one or more application-specific integrated circuits (ASICs). Hence, the features of the present invention described above may be implemented in hardware and/or software. For example, in some embodiments, the functional components of UE **101** described above may be implemented by data processing system **1202** executing computer instructions **1243**, by data processing system **1202** operating independent of any computer instructions **1243**, or by any suitable combination of hardware and/or software.

While the processes described above and illustrated in the drawings are shown as a sequence of steps, this was done solely for the sake of illustration. Accordingly, it is contemplated that some steps may be added, some steps may be omitted, the order of the steps may be re-arranged, and some steps may be performed in parallel.

The invention claimed is:

1. A method performed by a user equipment (UE) for providing to a network node channel station information, CSI, the method comprising:

receiving from the network node two measurement power offsets, a first measurement power offset (MPO) and a second MPO;

selecting one of said two measurement power offsets based on whether the network node has activated demodulation pilots for data demodulation, wherein the UE is configured to select the first MPO as a result of obtaining an indication that the network node has not activated the demodulation pilots for data demodulation and the UE is further configured to select the second MPO as a result of obtaining an indication that the network node has activated the demodulation pilots for data demodulation;

using the selected measurement power offset for CSI estimation; and

transmitting the CSI.

2. The method of claim 1, wherein

the method further comprises determining one or more of: a signal quality value, service type, and data rate, and the selecting one of said two measurement power offsets comprises selecting one of said two measurement power offsets based on one or more of the determined signal quality value, service type, and data rate.

3. The method of claim 1, wherein the method further comprises: selecting one of said two measurement power offsets based on an indication received from the network node.

4. The method of claim 1, wherein

the method further comprises the UE receiving an High-Speed Shared Control Channel, HS-SCCH, order,

the selecting one of said two measurement power offsets comprises selecting one of said two measurement power offsets based on the received HS-SCCH order.

13

5. The method of claim 1, wherein the two measurement power offsets are received via a radio resource control, RRC, message.

6. The method of claim 1, further comprising transmitting to a network node information identifying the selected measurement power offset.

7. A user equipment, UE, the UE comprising a data storage system and a data processing system, the data storage system comprising instructions executable by the data processing system whereby the UE is configured to:

receive from a network node two measurement power offsets, a first measurement power offset and a second measurement power offset;

select one of said two measurement power offsets based on whether the network node has activated demodulation pilots for data demodulation, wherein the UE is configured to select the first measurement power offset (MPO) as a result of obtaining an indication that the network node has not activated the demodulation pilots for data demodulation and the UE is further configured to select the second MPO as a result of obtaining an indication that the network node has activated the demodulation pilots for data demodulation;

use the selected measurement power offset for channel station information, CSI, estimation; and transmit the CSI.

8. The UE of claim 7, wherein

the UE is further configured to determine one or more of: a signal quality value, service type, and data rate, and the UE is configured to perform the selecting of one of said two measurement power offsets based on one or more of the determined signal quality value, service type, and data rate.

9. The UE of claim 7, wherein the UE is further configured to select one of said two measurement power offsets based on an indication received from the network node.

10. The UE of claim 7, wherein the UE is further configured to transmit to a network node information identifying the selected measurement power offset.

11. The UE of claim 7, wherein

the UE is further configured to receive an High-Speed Shared Control Channel, HS-SCCH order, and the UE is configured to perform the selecting of one of said two measurement power offsets based on a received HS-SCCH order.

12. A method performed by a network node for providing measurement power offsets to a user equipment, UE, the method comprising:

computing a first measurement power offset, Γ_1 , based on a first scheme, scheme-1;

computing a second measurement power offset, Γ_2 , based on a second scheme, scheme-2;

informing the UE of Γ_1 and Γ_2 , wherein

determining the first measurement power offset Γ_1 based on the scheme-1 comprises calculating:

$$\Gamma_1 = P_{HSPDSCH} - P_{CPICH}$$

determining the first measurement power offset Γ_2 based on the scheme-2 comprises calculating:

$$\Gamma_1 = P_{HSPDSCH} - P_{CPICH} - P_{DPICH}$$

$P_{HSPDSCH}$ denotes a total transmit power of a High-Speed Physical Downlink Shared Channel, HS-PDSCH,

P_{CPICH} denotes a combined transmit power of a set of common pilots used for MIMO operation of High-Speed Downlink Shared Channel, HS-DSCH, and

14

P_{DPICH} denotes a combined transmit power of a set of demodulation pilots used for MIMO operation of HS-DSCH.

13. The method of claim 12, wherein informing the UE of Γ_1 and Γ_2 comprises sending to the UE at a first point in time a message comprising Γ_1 and sending to the UE at a second point in time a message comprising Γ_2 , the second point in time being different than the first point in time.

14. The method of claim 12, wherein

the UE is configured to: i) select one of Γ_1 and Γ_2 and ii) compute channel state information (CSI) using the selected measurement power offset, and

the method further comprises: i) the network node receiving from the UE the computed CSI and ii) the network node determining the measurement power offset the UE used in computing the CSI.

15. The method of claim 12, further comprising transmitting to the UE an HS-SCCH order, wherein the UE is configured to use the HS-SCCH order to select one of Γ_1 and Γ_2 .

16. The method of claim 12, further comprising determining, based on one or more criteria, which of Γ_1 and Γ_2 the UE should use in computing CSI; and after determining the measurement power offset that the UE should use, transmitting to the UE information indicating the determined measurement power offset.

17. The method of claim 16, wherein determining which of Γ_1 and Γ_2 the UE should use in computing CSI comprises determining one or more of: a downlink signal quality, a service type, a data rate.

18. The method of claim 12, wherein the step of informing the UE of Γ_1 and Γ_2 comprises transmitting directly to the UE a message comprising Γ_1 and Γ_2 .

19. The method of claim 12, wherein

the step of informing the UE of Γ_1 and Γ_2 comprises sending to a radio network controller, RNC, a message comprising Γ_1 and Γ_2 ,

the RNC is configured to send Γ_1 and Γ_2 to the UE in response to receiving Γ_1 and Γ_2 from the network node, and

the network node is a base station.

20. A network node, the network node comprising a data storage system and a data processing system, the data storage system comprising instructions executable by the data processing system whereby the network node is configured to:

compute a first measurement power offset, Γ_1 , based on a first scheme, scheme-1;

compute a second measurement power offset, Γ_2 , based on a second scheme, scheme-2; and

inform the UE of Γ_1 and Γ_2 , wherein

computing the first measurement power offset Γ_1 based on the scheme-1 comprises calculating:

$$\Gamma_1 = P_{HSPDSCH} - P_{CPICH}$$

computing the first measurement power offset Γ_2 based on the scheme-2 comprises calculating:

$$\Gamma_2 = P_{HSPDSCH} - P_{CPICH} - P_{DPICH}$$

$P_{HSPDSCH}$ denotes a total transmit power of a High-Speed Physical Downlink Shared Channel, HS-PDSCH,

P_{CPICH} denotes a combined transmit power of a set of common pilots used for MIMO operation of High-Speed Downlink Shared Channel, HS-DSCH, and

P_{DPICH} denotes a combined transmit power of a set of demodulation pilots used for MIMO operation of HS-DSCH.

15

21. A method performed by a first network node for sending to a user equipment, UE, a first measurement power offset, Γ_1 , and a second measurement power offset, Γ_2 , the method comprising:

receiving Γ_1 and Γ_2 from a calculating node that calculated Γ_1 and Γ_2 , wherein the Γ_1 and Γ_2 are calculated based on a first scheme, scheme-1, and a second scheme, scheme-2, respectively;

including Γ_1 and Γ_2 in a message; and

transmitting the message so that the UE will receive Γ_1 and Γ_2 , wherein

the calculating node calculates the first measurement power offset Γ_1 based on the scheme-1 by calculating:

$$\Gamma_1 = P_{HSPDSCH} - P_{CPICH}$$

the calculating node calculates the second measurement power offset Γ_2 based on the scheme-2 by calculating:

$$\Gamma_2 = P_{HSPDSCH} - P_{CPICH} - P_{DPICH}$$

$P_{HSPDSCH}$ denotes a total transmit power of a High-Speed Physical Downlink Shared Channel, HS-PDSCH,

16

P_{CPICH} denotes a combined transmit power of a set of common pilots used for MIMO operation of High-Speed Downlink Shared Channel, HS-DSCH, and

P_{DPICH} denotes a combined transmit power of a set of demodulation pilots used for MIMO operation of HS-DSCH.

22. The method of claim 21, wherein

transmitting the message comprises transmitting the message to a second network node that is configured to transmit to the UE Γ_1 and Γ_2 after receiving the message,

the first network node is a first Radio Network Controller, RNC,

the second network node is a second RNC, and

the calculating node is a base station.

23. The method of claim 21, wherein

Γ_1 and Γ_2 are received from the calculating node via an Iub interface (117), and the message is a Radio Resource Control, RRC, message.
